

1 **"Tissue Repair"**

2

3 **Field of the Invention**

4

5 The present invention relates to methods of and
6 compounds for repairing tissue where the
7 extracellular matrix is degraded. More particularly,
8 the invention relates to compounds including
9 antibodies which increase extracellular matrix
10 anabolism and the identification of a novel pathway
11 to identify compounds which are capable of being used
12 in therapy to increase extracellular matrix
13 anabolism.

14

15 **Background to the Invention**

16

17 The Extracellular Matrix: Composition and Structure

18 The extracellular matrix (ECM) is a complex composite
19 of proteins, glycoproteins and proteoglycans (PGs).

1 Awareness of this complexity has been heightened by
2 the recognition that ECM components, individually or
3 in concert with each other or other extracellular
4 molecules, profoundly influence the biology of the
5 cell and hence of the physiology of the whole
6 structure in to which the cell is embedded. The
7 functions of the ECM described so far are many but
8 can be simply categorised as control of cell growth,
9 providing structural support and physical
10 stabilization, affecting cell differentiation,
11 orchestrating development and tuning metabolic
12 responses (42).

13

14 PGs are a family of heterogeneous and genetically
15 unrelated molecules. The number of full-time as well
16 as part-time members is constantly expanding. The
17 terms 'full-time' and 'part-time' refer to the fact
18 that some known PGs can exist as glycoproteins and
19 some proteins can be found in a glycosylated form.
20 In general, PGs are composed of a core protein to
21 which one or more Glycosaminoglycan (GAG) chains are
22 covalently attached by N or O linkage. GAGs are
23 highly anionic linear heteropolysaccharides made of a
24 disaccharide repeat sequences (53). However, there
25 have been reports of PGs devoid of the GAG side chain
26 (4; 106). GAGs can be classified into four distinct
27 categories based on their chemical composition (53).
28 The first category is the chondroitin/dermatan
29 sulphate (CS/DS) chain consisting of alternating

1 galactosamine and glucuronic/iduronic acid units. A
2 second class, which is by far the most structurally
3 diverse, is the heparin/heparan sulphate (H/HS) group
4 which is composed of alternating glucosamine and
5 glucuronic/iduronic repeats. The third type is the
6 glucosamine and galactose containing keratan sulphate
7 (KS) GAG. Hyaluronic acid (HA) is composed of
8 glucosamine and glucuronic acid repeats. It is the
9 most distinct GAG since it is not sulphated and is
10 not covalently linked to the core protein of PG.
11 Instead, HA binding to the PG core protein is
12 mediated by a class of proteins known as HA binding
13 proteins which exist in the ECM, on the cell surface
14 and intracellularly (93).
15
16 Perlecan is a large HSPG with a core protein size of
17 400-450 kDa known to possess three HS chains. It was
18 first isolated by Hassell et al.(44). It acquired
19 its name from its appearance in rotary shadowing
20 electron microscopy where it looks like a pearl on a
21 string. It is a large multi-domain protein and thus
22 one of the most complex gene products (23; 52).
23 Domain I is the N-terminus, this containing acidic
24 amino acid residues which facilitate the
25 polymerisation of heparan sulphate (52). However,
26 recombinant domain I has been shown to accept either
27 HS or CS chains; an observation that has been
28 confirmed by *in-vitro* studies characterizing PGs
29 synthesized in response to transforming growth factor

1 β (TGF- β) and foetal calf serum showing that perlecan
2 can be synthesized with CS chains (13). Ettner et
3 al. (26) have shown that the ECM glycoprotein
4 laminin, binds to perlecan domain I, as well as
5 domain V both of which can carry the HS side chain.
6 Loss of the HS chain abolished the binding.

7
8 Globular domain II was postulated to mediate ligand
9 binding by the low-density lipoprotein (LDL) receptor
10 due to their homology (30; 79). Heparitinase
11 treatment abrogates this interaction pointing to the
12 fact that the HS GAG side chains are involved in the
13 binding (30).

14
15 Domain III of perlecan contains an RGD tripeptide
16 sequence that provides a binding capacity for
17 integrin receptors and provides anchorage for the
18 cell (18). Yamagata et al. have shown using double-
19 immunofluorescence that perlecan colocalizes with
20 integrins in cultured fibroblasts (104). This domain
21 has also been shown to be homologous to the laminin
22 short arm (51).

23
24 Domain IV is the largest domain of perlecan
25 containing a series of immunoglobulin (Ig)-like
26 repeats similar to those found in the Ig superfamily
27 of adhesion molecules leading to the speculation that
28 it may function in intermolecular interactions (47).
29 Finally, domain V possessing three globular domains

1 homologous to the long arm of laminin is thought to
2 be responsible for self-assembly and laminin mediated
3 cell adhesion (14).

4

5 The multiplicity and variety of perlecan's structural
6 domains are indicative of its potential functions.
7 Perlecan, in addition to binding to laminin and
8 integrins, has been shown to bind fibronectin via its
9 core protein (51). The HS chains of perlecan also
10 have a very important functional role which has
11 proven to be diverse. It has been reported that
12 perlecan mediates the interaction between skeletal
13 muscle cells and collagen IV via the HS GAG side
14 chain (98). Recent studies have led to the
15 identification and characterization of perlecan as a
16 ligand for L-selectin in the kidney (65). Whether
17 this interaction is via the core protein and/or the
18 HS side chain is not clear. The group of Varki has
19 identified in a series of experiments the HS GAG as
20 well as heparin from endothelial cells as a ligand
21 for both L- and P- selectins but not E-selectins (59;
22 80). The HS side chains in general, and those
23 attached to perlecan core protein in particular, are
24 known to bind growth factors such as fibroblast
25 growth factors (FGF)-2, FGF-7, TGF- β , platelet
26 factor-4 and platelet-derived growth factor-BB (PDGF-
27 BB) (31; 52). The functional significance of these
28 interactions has been highlighted by numerous studies
29 demonstrating the role of perlecan in angiogenesis

1 (5; 87), the control of smooth muscle cell growth
2 (10) and the maturation and maintenance of basement
3 membranes (19). The functional importance of
4 perlecan has been demonstrated by a study of mice
5 lacking perlecan gene expression (19). Homozygous
6 null mice died between embryonic days 10 and 12. The
7 basement membranes normally subjected to increased
8 mechanical stresses such as the myocardium lost their
9 integrity and as a result small clefts formed in the
10 cardiac muscle leading to bleeding in the pericardial
11 sac and cardiac arrest. The homozygotes also had
12 severe cartilage defects characterised by
13 chondrodysplasia despite that fact that it is a
14 tissue which normally lacks basement membrane. This
15 finding was interpreted as a potential proteolysis-
16 protective function for perlecan in cartilage (19).
17 The delay in detecting abnormalities untill E10
18 suggests a certain redundancy with compensatory
19 molecules being able to substitute for perlecan such
20 as the basement membrane HSPGs collagen XVIII (38)
21 and agrin (36).

22

23 Large aggregating PGs are, to date, composed of four
24 members; versican, aggrecan, neurocan and brevican
25 (52). The hallmark of these PGs is the ability to
26 bind hyaluronic acid forming highly hydrated
27 aggregates. They are also characterized by their
28 tridomain structure composed of an N-terminal domain

1 where HA binding occurs, a central domain carrying
2 the GAG side chains and lectin binding C-terminus.

3

4 Versican is a PG with a core protein of 265 - 370 kDa
5 which was originally isolated from human fibroblasts
6 and is the homolog of the avian PG-M (110). It can
7 possess 10-30 chains of CS and has been also reported
8 to carry KS GAG chains (109). It is expressed by
9 keratinocytes, smooth muscle cells of the vessels,
10 brain and mesengial cells of the kidney. The N-
11 terminal domain is responsible for the hyaluronic
12 acid binding properties of versican (61). The
13 central domain of versican consists of the GAG
14 binding subdomains, GAG- α and GAG- β . These
15 subdomains are encoded by two alternatively spliced
16 exons and this gives rise to different versican
17 isoforms. To date four isoforms have been
18 recognized. V0 contains both GAG- α and GAG- β . V1 and
19 V2 are known to possess domain GAG- β and GAG- α
20 respectively (109). V3 is the variant which contains
21 neither of the two subdomains and hence carries no
22 CS/DS GAG side chains and has been localized in
23 various mammalian tissues (63; 82; 105). The third
24 domain of versican is the C-terminus and consists of
25 a lectin-binding domain, an EGF-like domain and a
26 complement regulatory protein-like domain. This C-
27 terminus binds the ECM glycoprotein, tenascin (3),
28 heparin and heparan sulphate (88) and fibulin (2).
29 Versican is known to have an inhibitory effect on

1 mesenchymal chondrogenesis (108), promotes
2 proliferation (107) and migration via the formation
3 of pericellular matrices via its interaction with
4 cell surface bound hyaluronic acid (27). The
5 formation of pericellular matrices is not only
6 achieved via the core protein association with HA but
7 also through GAG side chain interaction with the
8 cytoskeletal associated cell surface receptor, CD44
9 (55). The postulated role of versican in migration
10 has been also further reinforced by the recent
11 findings of its interaction with both L- and P-
12 selectins via the CS/DS side GAG chains (56).
13 Furthermore, versican GAG side chains modulate
14 chemokine response (45) and has been recently
15 reported to possess growth factor binding capacity
16 (111) and binding to β_1 integrin Wu, Chen, et al.
17 2002 394 .

18

19 Aggrecan is another large aggregating proteoglycan.
20 It is known to be a major structural component of
21 cartilage. It is composed of three globular domains
22 and two GAG attachment domains (100). The N-
23 terminal globular domain (G1) binds HA and link
24 protein to form large aggregates. The second
25 globular (G2) domain is unique to aggrecan and has no
26 HA binding capacity. The function of this domain has
27 not been clearly defined. The interglobular domain
28 between the G1 and G2 contains proteolytic cleavage
29 sites for metalloproteinases and thus been heavily

1 investigated in pathologies where degradation of this
2 domain is a hallmark, such as osteoarthritis. A KS
3 domain is located at the C-terminus of the G2 domain
4 followed by the CS domain. The CS domain is the
5 largest domain of aggrecan and the domain which
6 contributes to the hydrated gel-like forming capacity
7 of aggrecan and thus its importance in load-bearing
8 function. The last domain is the globular domain
9 (G3) which contains three modules: an epidermal
10 growth factor-like domain, a lectin module and a
11 complement regulatory module. This domain is
12 responsible for the interaction of aggrecan with the
13 ECM glycoprotein, tenascin.

14

15 **Functions of Extracellular Matrix Proteoglycans**

16

17 In addition to contributing to the mechanical
18 properties of connective tissues, extracellular matrix
19 (ECM) PGs have biological functions which are
20 achieved via specific classes of surface receptors.
21 The two main classes are the syndecan and integrin
22 receptor families (42). However, other receptors
23 have also been described to bind ECM components such
24 as the selectin family of glycoproteins (80), CD44
25 with all its variants (33), cell surface enzymes such
26 as hyaluronic acid synthases (89), and PGs (52). The
27 effects of the ECM do not and cannot, in an *in vivo*
28 milieu, ever occur without the influence of other
29 molecules. This statement is based on two well-

1 described concepts. The first being that part of the
2 effects of growth factors, cytokines, hormones and
3 vitamins, as well as cell-to-cell contact and
4 physical forces is alteration of the ECM production.
5 The second concept is that the effects of the ECM on
6 the cell bear a striking similarity to those effects
7 observed in response to the above mentioned factors.
8 This is a phenomenon known as "mutual reciprocity"
9 (42) which is an oversimplified view of a complex set
10 of modular interactions, i.e. as defined by Hartwell
11 et al. (43) "cellular functions carried out by
12 "modules" made up of many species of interacting
13 molecules". The outcome is a summation of all these
14 modules which often interact with each other in a
15 non-vectorial manner.
16
17 Integrins are a family of α , β heterodimeric receptors
18 that mediate dynamic linkages between extracellular
19 adhesion molecules and the intracellular actin
20 cytoskeleton. Although integrins are expressed by
21 all multicellular animals, their diversity varies
22 widely among species (49; 73; 94). To date 19 α and 8
23 β subunit genes encode polypeptides that combine to
24 form 25 different receptors. Integrins have been the
25 subject of extensive research investigating the
26 molecular and cellular basis of integrin function.
27 Integrins are major contributors to both the
28 maintenance of tissue integrity and the promotion of
29 cellular migration. Integrin-ligand interactions

1 provide physical support for cell cohesion,
2 generation of traction forces in cellular movement,
3 and organise signalling complexes to modulate
4 cellular functions such as differentiation and cell
5 fate. PGs are key ECM components which interact with
6 integrins modifying their function and integrins, in
7 turn, are key regulators of ECM PGs.

8
9 Currently little is known about the mechanisms
10 underlying tissue organisation and cellular
11 trafficking, and the regulation of those processes in
12 disease, as well as determining the molecular basis
13 of integrin function. No information has been
14 provided to identify the function of distinct regions
15 within the receptor.

16
17 Although numerous reports have employed functional
18 modification approaches using antibodies to $\beta 1$
19 integrin, the functional modification by definitions
20 remains obscure since it is mainly focused on
21 activation or blocking of adhesion to a substrate
22 under a defined set of conditions. The limitations of
23 such definition are clear. Firstly, it does not take
24 into account that unlike other receptors, integrins
25 can exist in an inactive, active and active and
26 occupied state. Secondly, the functional modulation
27 is often achieved via different domains and hence may
28 entail different downstream intracellular signalling
29 and therefore even if the effect on adhesion is

1 similar the functional end outcome can be different
2 since each region appears to possess a different
3 function (21; 48; 49; 72). Thirdly, $\beta 1$ integrin
4 exists in four different splice variants and the
5 difference is in the cytoplasmic domain hence
6 implicating different downstream signalling. The
7 difference in signalling downstream effects between
8 the splice variants is not yet defined. Therefore,
9 the use of functional modification terminology serves
10 best to take the above mentioned points into account
11 since the "blocking" and "activation" of adhesion
12 terminology refers to only one function, of many, of
13 integrin.

14
15 Heterodimers of $\beta 1$ integrin bind collagens ($\alpha 1, \alpha 2$),
16 laminins ($\alpha 1, \alpha 2, \alpha 3, \alpha 7, \alpha 9$) and fibronectin ($\alpha 3, \alpha 4, \alpha 5, \alpha 8, \alpha v$).
17 It can also act as a cell counter receptor for
18 molecules such as vascular cell adhesion molecule-1
19 (VCAM-1). Further more, recent reports have
20 demonstrated that $\beta 1$ integrin can also bind
21 metalloproteinases such as MMP2 (64) and MMP9 (28)
22 and affect their activation state. Both MMPs have
23 been shown to contribute to caspase-mediated brain
24 endothelial cell death after hypoxia-reoxygenation by
25 disrupting cell-matrix interactions and homeostatic
26 integrin signalling (7). TGF $\beta 1$ have also been
27 reported to bind to $\beta 1$ integrin.

28

1 The outside-in signaling of integrins is critical to
2 its numerous cellular functions such as adhesion,
3 proliferation, survival, differentiation, and
4 migration. The number and type of integrin receptors
5 heterodimer together with the availability of specific
6 ECM substrates are important in determining which
7 cellular functions are affected. The synthesis and
8 insertion of new integrins into the membrane, removal
9 from the cell surface, or both are possible
10 mechanisms for controlling the number of available
11 integrin receptors. It is possible that new synthesis
12 would require upregulation of expression and sorting
13 of specific α chains to pair with excess $\beta 1$ in the
14 cytoplasm and presentation of the new α/β heterodimer
15 in a precise location on the cell surface, which is
16 not a very targeted mechanism. An alternative method
17 of regulation could be cleavage at the cell surface,
18 or shedding, as an immediate method for removal of
19 specific integrin-ECM contacts as it would provide a
20 more focused mechanism for regulating specific
21 functions. Furthermore, the shed $\beta 1$ fragment could
22 bind to cells or ECM components or alternatively be
23 involved in signalling and biological events involved
24 in cellular growth and remodelling. Indeed it has
25 been shown that in myocytes and fibroblasts a change
26 size and shape results in altered cellular contacts
27 with the ECM. This lead to shedding of a $\beta 1$ integrin
28 fragment from the cell surface (32).
29

1 As to the role of $\beta 1$ integrin in tissue injury and
2 repair, it has been shown to be significantly
3 activated in the infarcted myocardium. Integrin $\beta 1$ is
4 active particularly at sites of inflammation and
5 fibrosis (90). Integrins- and cytoskeletal-associated
6 cytoplasmic focal adhesion proteins have been
7 suggested to participate in the process of
8 endothelial wound closure where treatment of human
9 coronary artery endothelial cells with anti- $\beta 1$
10 integrin function-modifying antibody enhanced wound
11 closure (1). Further in vivo evidence have shown that
12 the loss of $\beta 1$ integrins in keratinocytes caused a
13 severe defect in wound healing. $\beta 1$ -null keratinocytes
14 showed impaired migration and were more densely
15 packed in the hyperproliferative epithelium resulting
16 in failure in re-epithelialisation. As a consequence,
17 a prolonged inflammatory response, leading to
18 dramatic alterations in the expression of important
19 wound-regulated genes was seen. Ultimately, $\beta 1$ -
20 deficient epidermis did cover the wound bed, but the
21 epithelial architecture was abnormal. These findings
22 demonstrate a crucial role of $\beta 1$ integrins in wound
23 healing (37).

24

25 Apoptosis is a form of cell death that eliminates
26 compromised or superfluous cells. It is controlled by
27 multiple signaling and effector pathways that mediate
28 active responses to external growth, survival, or

1 death factors. Cell cycle checkpoint controls are
2 linked to apoptotic enzyme cascades, and the
3 integrity of these and other links can be genetically
4 compromised in many diseases, such as cancer. The
5 defining characteristic of apoptosis is a complete
6 change in cellular morphology where the cell
7 undergoes shrinkage, chromatin margination, membrane
8 blebbing, nuclear condensation and then segmentation,
9 and division into apoptotic bodies which may be
10 phagocytosed. DNA fragmentation in apoptotic cells is
11 followed by cell death and removal from the tissue,
12 usually within several hours. It is worth noting that
13 a rate of tissue regression as rapid as 25% per day
14 can result from apparent apoptosis in only 2-3% of
15 the cells at any one time.

16

17 β 1 integrin has also been implicated in apoptosis
18 (76; 77; 101). Involvement of β 1 integrin in beta
19 Amyloid Protein (β -AP)-induced apoptosis in human
20 neuroblastoma cells (12). In the presence of either
21 collagen I degrees, fibronectin, or laminin, β -AP
22 toxicity was severely reduced. This protective effect
23 seems to be mediated by integrins, because
24 preincubation of neuroblastoma cells with antibodies
25 directed against β 1 and α 1 integrin subunits greatly
26 enhanced β -AP-induced apoptosis.

27

1 Loss of activity of the $\beta 1$ -integrin receptor in
2 hepatocytes, which controls adhesion to collagen, was
3 seen to precede this loss of adhesive ability.
4 Addition of the $\beta 1$ -integrin antibody (TS2/16) to
5 cells cultured with liver injury serum significantly
6 increased their adhesion to collagen, and prevented
7 significant apoptosis (78). However, this effect
8 seems controversial as experiments with an antibody
9 to integrin $\beta 1$ suggest that the collagen-chondrocyte
10 interactions are mediated through integrin $\beta 1$, and
11 these interactions may protect chondrocytes from
12 apoptosis (16).

13

14 It has been postulated that prior to the commitment
15 to apoptosis, signals initiated by the apoptotic
16 stimulus may alter cell shape together with the
17 activation states and/or the availability of
18 integrins, which promote matrix-degrading activity
19 around dying cells. This pathway may interrupt ECM-
20 mediated survival signaling, and thus accelerate the
21 the cell death program (64).

22

23

24

25 **Maintenance of the Extracellular Matrix**

26

27 ECM homeostasis is maintained under normal
28 physiological conditions by a fine balance between
29 degradation and synthesis orchestrated by matrix

1 metalloproteinase (MMPs) and tissue inhibitors of
2 metalloproteinase (TIMPs). This homeostasis is
3 critical in many physiological processes such as
4 embryonic development, bone growth, nerve outgrowth,
5 ovulation, uterine involution, and wound healing.
6 MMPs also have a prominent role in pathological
7 processes such as arthritis (66; 70; 84), chronic
8 obstructive pulmonary disease (17; 92) and
9 atherosclerosis (67). However, little is known about
10 how they are anchored outside the cell.
11

12 Mechanical forces are known to modulate a variety
13 of cell functions such as protein synthesis,
14 proliferation, migration or survival and by doing so
15 regulate tissue structure and function. The routes
16 by which mechanical forces influence cell activities
17 have been defined as mechanotransduction and include
18 the tensegrity structure model and signalling through
19 cell surface mechanoreceptors including ECM binding
20 molecules. The tensegrity structure model postulates
21 that a cell maintains a level of prestress generated
22 actively by the actin microfilaments and intermediate
23 filaments (68). This active stress element is
24 balanced by structures resisting compression, mainly
25 microtubules within the cell and components of the
26 ECM. Matrix remodelling in response to mechanical
27 forces is an adaptive response to maintain tensegrity
28 in mechanosensitive tissues including cartilage and
29 lung. *In-vivo* and *in-vitro* observations demonstrate

1 that mechanical stimulation is necessary to maintain
2 optimal cartilage and lung structure and function
3 (81; 81; 91; 103). Thus mechanical forces regulate
4 ECM composition which, in turn, will modify the
5 mechanical microenvironment in tissues in a mutually
6 reciprocal manner. This aspect provided a valuable
7 tool for investigating biological functions in vitro.

8

9 Extracellular Matrix Catabolism and Anabolism

10 The ECM provides structural support as well as
11 biological signals to almost every organ in the body.
12 In the lung, the ECM provides structural support and
13 acts as an adhesive as well as a guiding cue for
14 diverse biological processes. Collagens are the most
15 abundant ECM component in the lung constituting 60-
16 70% of lung interstitium followed by elastin and PGs
17 and glycoproteins (96).

18

19 The ECM composition of organs varies between the
20 different anatomical and structural sites.

21

22 Lung PGs have just recently begun to be
23 characterised. Perlecan and what is thought to be
24 bamacan have been found in all lung basement
25 membranes (20; 74). Of the SLR-PGs, lumican has been
26 shown to be predominant and mainly found in the ECM
27 of vessel walls and to a lesser extent in airway
28 walls and alveolar septa (22). Immunohistochemical
29 studies have demonstrated the presence of biglycan in

1 the peripheral lung, though in very small quantities,
2 where it is associated with airway and blood vessel
3 walls (9; 22; 24). Furthermore, biglycan was shown
4 to be associated with the epithelial cell layer
5 particularly during development. Decorin has been
6 localized to the tracheal cartilage, surrounding
7 blood vessels and airways, and interlobular septae
8 (9). However, Western analyses have demonstrated
9 that decorin expression in the lung parenchyma is
10 undetectable (22). Similarly, it was shown in this
11 study that fibromodulin expression is also
12 undetectable; an observation confirmed by the
13 undetectable mRNA levels for this PG by Westergren-
14 Thorsson et al. (102). The large aggregating PG,
15 aggrecan, is only found in tracheal cartilage
16 associated with HA in a complex stabilized by the
17 link protein (85). On the other hand, versican can
18 be found in small quantities in the airway and blood
19 vessel walls (29), associated with smooth muscle
20 cells (97) and fibroblasts (54), and has been co-
21 localized with elastin fibres (85). HA can be found
22 in tracheal cartilage (85), basolateral surfaces of
23 the bronchiolar epithelium and the adventitia of
24 blood vessels and airways (34; 35). The HA receptor,
25 CD44, is expressed mainly by airway epithelium and
26 alveolar macrophages (57; 62). Syndecans have been
27 reported to be heavily expressed by alveolar
28 epithelial cells (69).

1 The Importance of the Extracellular Matrix in Disease
2 Awareness of extracellular matrix importance has been
3 heightened by the recognition that it profoundly
4 influences the biology of the cell and hence, both
5 mechanically and biochemically, the physiology of the
6 whole structure in which the cell is embedded. There
7 may be a real lead to the development of a novel
8 therapeutic intervention where part of the clinical
9 presentation is precipitated by an imbalance in
10 catabolism vs anabolism such as may be found in
11 chronic obstructive pulmonary disease.

12
13 Chronic Obstructive Pulmonary Disease (COPD),
14 comprising chronic bronchitis and emphysema, is a
15 major cause of chronic morbidity and mortality
16 throughout the world. In the UK, COPD is the fifth
17 leading cause of death, causing 26,000 deaths and
18 240,000 hospital admissions annually. The cost to
19 the National Health Service of the UK of COPD-related
20 hospital admissions is in excess of £486 million
21 annually (15). Further costs are incurred due to co-
22 morbidity such as respiratory infections and
23 depression. Research into emphysema pathology and
24 its treatment has been largely neglected because of
25 the view that it is mainly self-inflicted.
26 Therefore strategies to effectively manage emphysema
27 are needed in parallel to health promotion.

28

29

1 The Pathology of COPD

2 COPD is characterised by a progressive and
3 irreversible airflow limitation (95) as a result of
4 small airway disease (obstructive bronchiolitis) and
5 parenchymal destruction (emphysema). Destruction of
6 lung parenchyma is characterised by the loss of
7 alveolar attachments to the small airways, decreased
8 lung elastic recoil and as a consequence diminished
9 ability of the airways to remain open during
10 expiration (8).

11

12 Although the main risk factor for COPD is tobacco
13 smoking, other predisposing factors have been
14 identified (86). Emphysema is caused by
15 inflammation, an imbalance of proteinases and
16 antiproteinases in the lung (typified by hereditary
17 α -1 antitrypsin deficiency) and oxidative stress
18 which leads to the destruction of the ECM.

19

20 Current Treatments for COPD and Emphysema

21 To date, the only available drug treatments for COPD
22 sufferers have focussed primarily on bronchodilation
23 using anticholinergics and dual β 2-dopamine2 receptor
24 antagonists. Inflammation in COPD is resistant to
25 corticosteroids. Metalloproteinase (MMP) inhibitors
26 are currently being developed to treat COPD, although
27 in their current formulation, serious toxic side
28 effect are almost certain to limit their use.
29 Retinoids have also been shown to induce alveolar

1 repair though this remain largely disputed. However,
2 notwithstanding all such hopeful activities, what is
3 clearly lacking is an agent which may aid in the
4 repair of injured ECM.

5

6 In summary, COPD/emphysema is a paradigm for diseases
7 which have a strong element of ECM remodelling as a
8 major contributor to their pathophysiology. Other
9 organs which require tissue repair include, but are
10 not limited to; skin, central nervous system, liver,
11 kidney, cardiovascular system, bone and cartilage.
12 Furthermore, current therapeutics have focused
13 primarily on preventative or symptom-relieving
14 treatments. However, due to the progressive nature of
15 both diseases together with often late diagnosis,
16 regaining normal function remains a problem.

17

18 Recently, novel therapeutic approaches targeting
19 integrin function have been adopted. Very late
20 antigen-4 (VLA4) or $\alpha 4$ integrin antagonists are
21 currently in advance stages of trials for the
22 treatment of asthma, multiple sclerosis and Crohn's
23 disease (58; 60; 71). Antagonists to $\alpha v \beta 3$ integrin
24 have attenuated adjuvant-induced arthritis and now
25 are undergoing trials (6). The target of the
26 functional blocking or antagonism is attenuating
27 inflammation and this has not been demonstrated to
28 affect the ECM alteration usually associated with
29 those conditions.

1

2 The inventors have now surprisingly shown that
3 compounds which modulate the function of beta 1
4 integrin facilitate improved tissue repair and
5 regeneration.

6

7 **Summary of the Invention**

8

9 According to the present invention there is provided
10 a method of promoting tissue repair, the method
11 comprising the step of administering a compound which
12 modulates the function of beta 1 integrin.

13

14 Preferably the compound functionally modulates the
15 activity of the beta 1 integrin. Without being bound
16 by theory, the inventors theorise that the modulation
17 of the beta 1 integrin which results from binding can
18 result in an alteration of the metalloproteinase
19 (MMP) balance, and / or inhibiting the apoptotic
20 pathway and related intracellular apoptotic activity
21 and signalling.

22

23 'Modification' or 'modulation' includes a change in
24 the function of, or the shedding, of the β 1 integrin.

25

26 It is thought that a compound according to the
27 present invention may also act by shedding the β 1
28 integrin and/or affecting MMPs/TIMPs balance, as

1 described above. Further the compound may affect the
2 apoptotic pathway.

3
4 As used herein, the term 'tissue repair' relates to
5 repair or regeneration of tissue following damage or
6 trauma.

7
8 The discovery that modulation of the beta 1 integrin
9 may be useful in tissue repair enables the provision
10 of further novel compounds useful for tissue repair.

11
12 Accordingly, a further aspect of the invention
13 provides a method of screening compounds for use in
14 tissue repair, the method including the step of
15 determining the ability of a compound to modify or
16 modulate the function of the beta 1 integrin.

17
18 Preferably the method includes the step of
19 determining the ability of a compound to bind the
20 domain corresponding to residues 82-87 of the mature
21 beta 1 (β 1) integrin. These residues have the
22 sequence as defined in SEQ ID NO:1, namely TAEKLLK
23 (Threonine-Alanine-Glutamic Acid-Lysine-Leucine-
24 Lysine).

25
26 A yet further aspect of the present invention
27 provides novel compounds identified from the assay
28 methods described herein which modulate the function
29 of beta 1 integrin.

1
2 The novel compounds of the present invention can be
3 used in tissue repair in any tissue, for example
4 tissue of the lung, skin, liver, kidney, nervous
5 system, cartilage, bone and cardiovascular system.
6

7 In one embodiment the novel compounds binds the beta
8 1 integrin molecule at amino acid sequence
9 corresponding to residues 82-87 of the mature beta 1
10 (β 1) integrin molecule. It is to be understood,
11 however, that this is not limiting and there are
12 other domains in the β 1 integrin molecule to which
13 compounds may bind.
14

15 In the known sequence, residues 82-87 are the
16 residues of the sequence identified by the
17 nomenclature SEQ ID NO 1: TAEKLLK (Threonine-Alanine-
18 Glutamic Acid-Lysine-Leucine-Lysine).
19

20 The compound may be a peptide or an analogue thereof
21 or alternatively be a chemical. The compound may
22 further be a synthetic peptide or a synthetic
23 chemical.
24

25 In a preferred embodiment the compound is an
26 antibody.
27

28 The antibody is preferably a humanised antibody.
29

1 The antibody may be a chimeric antibody.
2 Alternatively the antibody could be a human antibody.
3
4 In one embodiment the antibody may be based on or
5 derived from the functional modifying antibody of
6 β 1 integrin obtainable as produced by a commercial
7 clone JB1a from Chemicon (this antibody may also be
8 known as J10).
9
10 In a further embodiment the antibody could be based
11 on or derived from the antibody 6S6. 6SS targets a
12 domain of the β 1 integrin yet to be specifically
13 identified, but thought to be in the EGF-like repeat
14 domain distinct from the 82-87 domain of the mature
15 β 1 integrin molecule targeted by the JB1a antibody.
16
17 A yet further aspect of the present invention
18 provides a method of improving tissue repair and
19 regeneration, the method including the steps of:
20 - selecting a composition including a compound
21 capable of binding to beta 1 integrin or an
22 analogue thereof,
23 - administering a therapeutically useful amount
24 of the composition to a subject in need of
25 treatment.
26
27 Preferably a therapeutically useful amount of the
28 composition results in the binding of beta 1 integrin

1 such that its activity is modulated and tissue repair
2 and regeneration results.

3

4 A yet further aspect of the present invention
5 provides for a compound which modulates the function
6 of beta 1 integrin for use in tissue repair.

7

8 Such compounds may be used in the methods of the
9 invention.

10

11 A yet further aspect of the present invention
12 provides for the use of a compound which modulates
13 the function of beta 1 integrin in the preparation of
14 a medicament for the repair of tissue.

15

16 The invention further provides the use of an antibody
17 to beta 1 integrin in the preparation of a medicament
18 for the treatment of injured tissue administered via
19 any therapeutic route.

20

21 **Detailed Description**

22

23 **Treatment**

24 The term 'treatment' as used herein refers to any
25 regime that can benefit a human or non-human animal.

26 The treatment may be in respect of an existing
27 condition or may be prophylactic (preventative
28 treatment). Treatment may include curative,
29 alleviation or prophylactic effects.

1

2 **Antibodies**

3 An "antibody" is an immunoglobulin, whether natural
4 or partly or wholly synthetically produced. The term
5 also covers any polypeptide, protein or peptide
6 having a binding domain that is, or is homologous to,
7 an antibody binding domain and in particular the
8 antibody binding domains of the beta 1 integrin to
9 which the Jb1a antibody or 6SS antibody binds. Such
10 polypeptides, proteins or peptides can be derived
11 from natural sources, or they may be partly or wholly
12 synthetically produced. Examples of antibodies are
13 the immunoglobulin isotypes and their isotypic
14 subclasses and fragments which comprise an antigen
15 binding domain.

16

17 Antibodies for use in the invention, including for
18 example the Jb1a or 6S6 antibodies or analogues
19 thereof.

20

21 Analogues of such antibodies may be made by varying
22 the amino acid sequence of the antibody e.g. by
23 manipulation of the nucleic acid encoding the protein
24 or by altering the protein itself. Such derivatives
25 of the amino acid sequence may involve insertion,
26 addition, deletion and/or substitution of one or more
27 amino acids

28

1 Preferably such analogues involve the insertion,
2 addition, deletion and/or substitution of 5 or fewer,
3 and most preferably of only 1 or 2 amino acids.

4

5 Analogues also include derivatives of the peptide
6 sequences of the antibodies, including the peptide
7 being linked to a coupling partner, e.g. an effector
8 molecule, a label, a drug, a toxin and/or a carrier
9 or transport molecule. Techniques for coupling the
10 peptides of the invention to both peptidyl and non-
11 peptidyl coupling partners are well known in the art.

12

13 Analogues of and for use in the invention preferably
14 retain beta 1 integrin modulating activity.

15

16 Antibodies for use in the invention may be monoclonal
17 or polyclonal, or fragments thereof. The constant
18 region of the antibody may be of any class including,
19 but not limited to, human classes IgG, IgA, IgM, IgD
20 and IgE. The antibody may belong to any sub class
21 e.g. IgG1, IgG2, IgG3 and IgG4.

22

23 The term "antibody" includes antibodies which have
24 been "humanised". Methods for making humanised
25 antibodies are known in the art. Such methods are
26 described, for example, in Winter, U.S. Patent No.
27 5,225,539. A humanised antibody may be a modified
28 antibody having the hypervariable region of a
29 monoclonal antibody and the constant region of a

1 human antibody. Thus the binding member may comprise
2 a human constant region.

3
4 As antibodies can be modified in a number of ways,
5 the term "antibody" should be construed as covering
6 any binding member or substance having a binding
7 domain with the required specificity. Thus, this
8 term also covers antibody fragments, derivatives,
9 functional equivalents and homologues of antibodies,
10 including any polypeptide comprising an
11 immunoglobulin-binding domain, whether natural or
12 wholly or partially synthetic. Chimeric molecules
13 comprising an immunoglobulin binding domain, or
14 equivalent, fused to another polypeptide are
15 therefore included. Cloning and expression of
16 chimeric antibodies are described in EP-A-0120694 and
17 EP-A-0125023.

18
19 It has been shown that fragments of a whole antibody
20 can perform the function of antigen binding.

21
22 Examples of such binding fragments are (i) the Fab
23 fragment consisting of VL, VH, CL and CH1 domains;
24 (ii) the Fd fragment consisting of the VH and CH1
25 domains; (iii) the Fv fragment consisting of the VL
26 and VH domains of a single antibody; (iv) the dAb
27 fragment (99) which consists of a VH domain; (v)
28 isolated CDR regions; (vi) F(ab')₂ fragments, a
29 bivalent fragment comprising two linked Fab fragments

1 (vii) single chain Fv molecules (scFv), wherein a VH
2 domain and a VL domain are linked by a peptide linker
3 which allows the two domains to associate to form an
4 antigen binding site (11; 50); (viii) bispecific
5 single chain Fv dimers (PCT/US92/09965) and (ix)
6 "diabodies", multivalent or multispecific fragments
7 constructed by gene fusion (WO94/13804; (46)).

8
9 Substitutions may be made to the binding epitope of
10 antibodies for use in the invention for example amino
11 acid residues may be substituted with a residues of
12 the same or similar chemical class, and which result
13 in no substantial conformational change of the
14 binding epitope.

15
16 Antibodies of and for use in the invention can be
17 prepared according to standard techniques.

18 Procedures for immunising animals, e.g. mice with
19 proteins and selection of hybridomas producing
20 immunogen specific monoclonal antibodies are well
21 known in the art. The antibody is preferably a
22 monoclonal antibody.

23

24 **Pharmaceutical Compositions**

25 The present invention further extends to
26 pharmaceuticals and to pharmaceutical compositions
27 for the modulation of the function of the beta 1
28 integrin.

29

1 Accordingly, yet further aspect of the present
2 invention provides a pharmaceutical composition for
3 use in tissue repair wherein the composition includes
4 as an active ingredient, a compound which modifies
5 the function of beta 1 integrin.

6
7 Pharmaceutical compositions according to the present
8 invention, and for use in accordance with the present
9 invention may comprise, in addition to active
10 ingredient, a pharmaceutically acceptable excipient,
11 carrier, buffer stabiliser or other materials well
12 known to those skilled in the art. Such materials
13 should be non-toxic and should not interfere with the
14 efficacy of the active ingredient. The precise
15 nature of the carrier or other material will depend
16 on the route of administration.

17

18 **Dose**

19 The composition is preferably administered to an
20 individual in a "therapeutically effective amount",
21 this being sufficient to show benefit to the
22 individual. The actual amount administered, and rate
23 and time-course of administration, will depend on the
24 individual and condition being treated.

25

26 The optimal dose can be determined based on a number
27 of parameters including, for example the age of the
28 individual and the extent of tissue damage, the

1 precise form of the composition being administered
2 and the route of administration.

3

4 The composition may be administered via microspheres,
5 liposomes, other microparticulate delivery systems or
6 sustained release formulations placed in certain
7 tissues including blood. Suitable examples of
8 sustained release carriers include semipermeable
9 polymer matrices in the form of shared articles, e.g.
10 suppositories or microcapsules.

11

12 Examples of the techniques and protocols mentioned
13 above and other techniques and protocols which may be
14 used in accordance with the invention can be found in
15 Remington's Pharmaceutical Sciences, 18th edition,
16 Gennaro, A.R., Lippincott Williams & Wilkins; 20th
17 edition (December 15, 2000) ISBN 0-912734-04-3 and
18 Pharmaceutical Dosage Forms and Drug Delivery
19 Systems; Ansel, H.C. et al. 7th Edition ISBN 0-683305-
20 72-7 the entire disclosures of which is herein
21 incorporated by reference.

22

23 **Assays**

24 As described above, the invention provides assay
25 systems and screening methods for determining
26 compounds which may be used in tissue repair. As
27 used herein, an "assay system" encompasses all the
28 components required for performing and analysing

1 results of an assay that detects and/or measures a
2 particular event or events.

3

4 A variety of assays are available to detect the
5 activity of compounds such as antibodies, peptides
6 and chemicals which have specific binding activity to
7 beta 1 integrin.

8

9 The precise format of the assay(s) of the invention
10 may be varied by those skilled in the art using
11 routine skill and knowledge.

12

13 Preferred screening assays are high throughput or
14 ultra high throughput and thus provide automated,
15 cost-effective means of screening.

16

17 The discovery that modifications of beta 1 integrin
18 may be useful in tissue repair enables the
19 identification and of further novel compounds useful
20 for tissue repair.

21

22 Accordingly, a further aspect of the invention
23 provides an assay for identifying compounds suitable
24 for use in tissue repair, said assay comprising the
25 steps of:

- 26 - providing a candidate compound,
- 27 - bringing the candidate compound into contact
- 28 with beta 1 integrin or an analogue thereof,

1 - determining the presence or absence of
2 modulation of beta 1 integrin activity by the
3 candidate compound,
4 wherein modulation of beta 1 integrin activity is
5 indicative of utility of that compound in tissue
6 repair.

7
8 Preferably the method includes the step of
9 determining the ability of a compound to bind the
10 domain corresponding to residues 82-87 of the mature
11 beta 1 (β 1) integrin. These residues have the
12 sequence as defined in SEQ ID No:1, namely TAEKLLK
13 (Threonine-Alanine-Glutamic Acid-Lysine-Leucine-
14 Lysine).

15
16 In another embodiment, the presence or absence of
17 beta 1 integrin activity is assessed by monitoring
18 modulation of MMP activity.

19
20 Beta 1 integrin modulating activity may be assessed
21 in the assays of the invention using any suitable
22 means. For example, the effect of the agent on MMP
23 levels or balance, and / or the effect on apoptosis
24 and apoptotic pathways. Exemplary assays are western
25 blotting analyses and ELISA based assays for MMPs
26 protein in both active and inactive forms,
27 proteoglycans synthesis using western analyses and
28 ELISA based assays, cell adhesion based assays,

1 apoptosis assays using in-situ labelling,
2 immunohistochemistry and gel analyses.

3

4 In various further aspects, the present invention
5 relates to screening and assay methods and to
6 substances identified thereby.

7

8 Novel compounds identified using the assays of the
9 invention form a further independent aspect of the
10 invention.

11

12 In assays of the invention, analogues of beta 1
13 integrin may be used. Such analogues may comprise
14 one or more binding sites of beta 1 integrin, for
15 example the binding site corresponding to amino acid
16 residues 82 to 87 of the mature beta 1 integrin
17 molecule. Alternatively, the analogue may comprise a
18 beta 1 integrin mimetic. The skilled person is well
19 aware of how to design such a mimetic. Briefly, a
20 template molecule is selected onto which chemical
21 groups which mimic the pharmacophore can be grafted.
22 The template molecule and the chemical groups grafted
23 on to it can conveniently be selected so that the
24 mimetic is easy to synthesise, is likely to be
25 pharmacologically acceptable, and does not degrade
26 *in-vivo*, while retaining the biological activity of
27 the beta 1 integrin.

28

1 The mimetic found by this approach can then be used
2 in assays of the invention in place of beta 1
3 integrin to see whether they have a target property
4 eg. beta 1 integrin activity, or to what extent they
5 exhibit it. Further optimisation or modification can
6 then be carried out to arrive at one or more final
7 mimetics for *in-vivo* or clinical testing or for use
8 in the assays of the invention.

9
10 Preferred features of each aspect of the invention
11 are as for each other aspect, *mutatis mutandis*,
12 unless the context demands otherwise.

13
14 Unless otherwise defined, all technical and
15 scientific terms used herein have the meaning
16 commonly understood by a person who is skilled in the
17 art in the field of the present invention.

18
19 Throughout the specification, unless the context
20 demands otherwise, the terms 'comprise' or 'include',
21 or variations such as 'comprises' or 'comprising',
22 'includes' or 'including' will be understood to imply
23 the inclusion of a stated integer or group of
24 integers, but not the exclusion of any other integer
25 or group of integers.

26
27 The invention is exemplified herein with reference to
28 the following non limiting examples which are
29 provided for the purpose of illustration and are not

1 to be construed as being limiting on the present
2 invention. Further reference is made to the
3 accompanying figures wherein;

4

5 Figure 1 illustrates time-dependent effects of
6 functional modification of $\beta 1$ integrin and
7 neutralising TGF- β on ECM PG from H441 cell
8 lines,

9

10 Figure 2 shows the presence of a 110kDa $\beta 1$
11 integrin in the media of chondrocytes in
12 alginate cultures and H441 cells separated
13 onto 6% SDS-polyacrylamide gels following $\beta 1$
14 integrin function modulation,

15

16 Figure 3 illustrates the time-dependent effect
17 of functional modification of $\beta 1$ integrin on
18 ECM PGs in human lung explants and the lack of
19 effect using a control $\beta 1$ integrin antibody,

20

21 Figure 4 illustrates the effects of functional
22 modification of $\beta 1$ integrin on ECM PGs in
23 human lung explants,

24

25 Figure 5 shows Western analyses demonstrating
26 the increase in inactive MMP9 in the media of
27 human lung explants following $\beta 1$ integrin
28 function modulation,

1
2 Figure 6 shows Western analyses demonstrating
3 the increase in ECM PG, perlecan in the media
4 of cultured human lung cells (Collagenase
5 digest alone or in co-culture with the
6 Elastase digests) following $\beta 1$ integrin
7 function modulation ($\beta 1$ Ab). The figure also
8 shows the effect of cycloheximide (CXH) and
9 APMA on the PG response to $\beta 1$ integrin
10 function modulation. In addition, the effect
11 of neutralising MMP7 and 9 and MMPs are
12 demonstrated,

13
14 Figure 7 shows Western analyses demonstrating
15 the increase in TIMP1 in the media of cultured
16 human lung cells (Collagenase digest alone or
17 in co-culture with the Elastase digests)
18 following $\beta 1$ integrin function modulation ($\beta 1$
19 Ab). The figure also shows the effect of
20 cycloheximide (CXH) and APMA on the TIMP1
21 response to $\beta 1$ integrin function modulation.
22 In addition, the effect of neutralising MMP7
23 and 9 and MMPs are demonstrated,

24
25 Figure 8 shows Western analyses demonstrating
26 the decrease in MMP1 in the media of cultured
27 human lung cells (Collagenase digest alone or
28 in co-culture with the Elastase digests)

1 following $\beta 1$ integrin function modulation ($\beta 1$
2 Ab). The figure also shows the effect of
3 cycloheximide (CXH) and APMA on the TIMP1
4 response to $\beta 1$ integrin function modulation.
5 In addition, the effect of neutralising MMP7
6 and 9 and MMPs are demonstrated,

7
8 Figure 9 shows Western analyses demonstrating
9 the increase in inactive MMP9 in the media of
10 cultured human lung cells (Collagenase digest
11 alone or in co-culture with the Elastase
12 digests) following $\beta 1$ integrin function
13 modulation ($\beta 1$ Ab). The figure also shows the
14 effect of cycloheximide (CXH) and APMA on the
15 TIMP1 response to $\beta 1$ integrin function
16 modulation. In addition, the effect of
17 neutralising MMP7 and 9 and MMPs are
18 demonstrated,

8 and the significance of the correlations
9 between the lung physiological measurements
10 and the mean linear intercept (Lm).
11

12 In a preliminary experiment, the present inventors
13 attempted to investigate the role of the cell surface
14 receptors in the synthesis of ECM which are altered
15 in diseases such as COPD and are important for lung
16 and cartilage function microscopically and
17 macroscopically. The importance of those ECM
18 molecules in health and disease is not exclusive to
19 the lung.

20
21 The results described herein demonstrate that
22 functional modification of $\beta 1$ integrin through a
23 domain corresponding to amino acid residues 82 to 87
24 and to a lesser extent through a domain not yet
25 specifically identified, but thought to be in the
26 EFG-like repeat domain distinct from the 82 to 87
27 domain, induces a substantial time- and dose-
28 dependent increase in ECM in a human lung epithelial
29 cell line (NCI-H441) in monolayer and human lung

1 explants as well as human lung derived culture in
2 monolayer or co-culture system. The response was
3 observed using two different antibodies against $\beta 1$
4 integrin though the magnitude of the response was
5 variable. These domains are different from those
6 previously described which bind to the amino acid
7 sequence residues 207 to 218. It is also distinct
8 from the known stimulatory domains which are
9 localised to those amino acid residues and residues
10 657 to 670 and 671 to 703. Modulation of the
11 cytokine TGF- β induced a less profound increase which
12 was also time- and dose-dependent. This increase in
13 all ECM PGs was sustained for extended periods of
14 time without any additive doses.

15

16 These experiments demonstrate a novel finding which
17 is that an increase in ECM can be achieved via the
18 modulation of cell surface receptors and to a much
19 lesser extent by modulating the binding of a soluble
20 factor in a time- and dose-dependent manner in
21 pulmonary derived cells and tissues in animal models.
22 Potential, but non-binding mechanistic hypotheses are
23 that this modulation may have led to alteration in
24 the cell adhesion its damaged surroundings and thus
25 prevented cell death permitting repair to ensue. This
26 alteration in turn may affect the proteinase /
27 antiproteinase balance which can be sequestered onto
28 the surface of cells. Furthermore, the response could
29 be a result of changes in gene transcription or

1 translation. Our experiments have demonstrated that
2 the response is due to combination of all the above.
3 The ECM response to $\beta 1$ integrin functional
4 modification was accompanied by a decrease in cell
5 death and increase in TIMP1, inactive MMP9 and active
6 TGF β 1 and a decrease in MMP1.

7
8 When administered to animals which have emphysematous
9 lungs, the treatment reversed the abnormal increase
10 in the mean linear intercept (LM) as an index of air
11 space enlargement, lung size and abnormal lung
12 function as well as signs of inflammation.
13 Furthermore, there was a decrease in cell death.

14
15 The potential of these findings lie in tissue repair
16 in disease where the matrix is degraded and cannot be
17 replenished as in diseases that include but not
18 exclusive to COPD. The finding may offer a venue for
19 therapeutic intervention in diseases where the only
20 current lines of therapy focus on alleviating the
21 symptoms by the use of anti-inflammatory agents but
22 has no potential for regaining function. This could
23 be achieved via the administration of humanised,
24 chimeric or human antibodies or synthetic peptides or
25 chemicals capable of binding $\beta 1$ integrin and
26 inhibiting cell death.

27
28 In summary, the results herein address a different
29 potential therapeutic modality which focuses on

1 increasing cell viability and ECM anabolism instead
2 of decreasing catabolism.

3

4 **EXPERIMENTAL PROTOCOL**

5

6 **Human lung explants culture and human lung derived** 7 **cell isolation**

8

9 Human lung tissue specimens were obtained with
10 consent and cultured as either 20-30mg explant strips
11 or cells.

12

13 Cell were isolated by sequential digestions modified
14 from methods by Murphy et al. and Elbert et al. (25;
15 75) where the tissue (10g) was washed using HEPES
16 buffer (buffer A: 0.13M NaCl, 5.2mM KCl, 10.6mM
17 Hepes, 2.6mM Na₂HPO₄, 10mM D-glucose, pH 7.4). The
18 tissue was then incubated in 40 ml buffer A
19 containing 0.855 mg Elastase (Roche) 0.5% trypsin,
20 200U/g DNaseI, 1.9mM CaCl₂, and 1.29mM MgSO₄ for 40
21 minutes at 37°C.

22

23 The digest buffer is then aspirated and suspended
24 cells washed three times in buffer A. The cells
25 between each wash were pelleted by centrifuging the
26 suspension for 10 minutes at 1100rpm and 4°C. After
27 the final wash the cells were resuspended in buffer A,
28 filtered through 40um filter and then subjected to
29 discontinuous Percoll gradient (1.089/1.04g/ml). The

1 cells were then plated onto multi-well culture plates
2 and tissue culture transwells of 0.3um pore
3 size(Sigma) and maintained in culture using 1:1
4 DMEM/F12:Small airway growth media (Cambrex BioScience
5 Wokingham Ltd.) containing 1% foetal calf serum L-
6 glutamine and antibiotic/antimycotic/antifungal
7 mixture and maintained at 5% in an CO₂ incubator.

8
9 The remaining tissue was treated with DMEM containing
10 40% foetal calf serum to inactivate the digestive
11 enzymes and then washed using solution A. The tissue
12 was then incubated in DMEM containing 1mg/ml
13 Collagenase, 0.5% trypsin and 200U/g DNaseI and
14 maintained at 5% in an CO₂ incubator. The cell
15 suspension was washed as above and cells seeded on
16 multiwell culture plates and maintained in DMEM
17 (Sigma Aldrich) containing 10% foetal calf serum, L-
18 glutamine and antibiotic/antimycotic/antifungal
19 mixture and maintained at 5% in a CO₂ incubator.

20
21 Adenocarcinoma cell line derived from the lung were
22 also used (H441) to test the effect of the antibodies
23 on matrix synthesis. This cell line has epithelial
24 type II characteristics.

25
26 Cultures were subjected to serum starving overnight
27 in a medium containing 0.5% foetal calf serum. Some
28 collagenase digested plated were co-culture with the

1 Elastase digest transwells at the time of initiating
2 the starvation.
3
4 Functional modifying antibody of $\beta 1$ integrin
5 (Chemicon, clone JB1a) was added to the cultures at
6 concentration of 1.44 and 0.48 $\mu\text{g/ml}$. The $\beta 1$
7 integrin stimulatory antibody TS2/16 was also added
8 at 0.9 $\mu\text{g/ml}$ for 1 hour to demonstrate the
9 specificity of the JB1a action. The $\beta 1$ integrin
10 inhibitory antibody 6S6 was also added at 1 $\mu\text{g/ml}$ and
11 2 $\mu\text{g/ml}$ for 1 hour. TGF β neutralising antibody (R&D
12 systems, clone 1D11) was added at a concentration of
13 0.1 and 0.3 $\mu\text{g/ml}$ where at the lower concentration it
14 neutralises TGF β isoforms 1 and 3 and isoform 2 at
15 the higher concentration. After antibody addition to
16 the cells in culture, the medium was aspirated and
17 the cell layer rinsed twice with ice-cold PBS
18 (calcium- and magnesium-free). The media was
19 aspirated and preserved after the addition of
20 protease inhibitors at -80°C . PGs were extracted
21 from the cell layer by extraction buffer containing
22 protease inhibitors (4M guanidium-HCl, 4% (w/v)
23 CHAPS, 100mM sodium acetate buffer at pH 5.8
24 containing protease inhibitors) for 24 hours at 4°C .
25
26 In additional experiments, the effect of protein
27 synthesis inhibition on $\beta 1$ integrin mediated PG

1 increase was tested by pretreating the human lung
2 derived cells with 25uM cycloheximide.

3

4 The effect of non-specific activation of MMPs on β 1
5 integrin mediated PG increase was tested by
6 pretreating the human lung derived cells with 0.5M
7 APMA (aminophenylmercuric acetate).

8

9 To investigate the involvement of selected MMPs in
10 initiating the response observed with β 1 integrin,
11 specific neutralising antibodies for MMP7 (1:1000,
12 R&D systems) and MMP9 (1:1000 of clone 6-6B, Oncogene
13 Research Products. A homophe-hydroxamic acid based
14 broad spectrum inhibitor of MMPs was also used at
15 2.3nM (MMP inhibitor III, Calbiochem).

16

17 The total protein concentration was estimated using
18 the Bradford method.

19

20 **Sample Preparation for Composite Polyacrylamide-**
21 **Agarose Gel Electrophoresis**

22

23 The extracts were precipitated overnight with 9 v/v
24 ethanol at -20°C, centrifuged at 12,000 rpm for
25 40minutes at 4°C then resuspended in 0.5M sodium
26 acetate (pH 7.3) and precipitated again with ethanol
27 overnight and centrifuged. Samples were resuspended
28 in 0.5% SDS and mixed with 1:1 v/v with 50%w/w
29 sucrose in 10mM Tris-HCl (pH 6.8), 0.5% SDS and 0.05%

1 bromophenol blue. 20ug of protein was used for gel
2 loading.

3

4 **Gel electrophoresis**

5

6 Composite gels (1.5mm thick) containing 0.6% agarose
7 and 1.2% polyacrylamide in Tris-sodium acetate buffer
8 (10mM, pH 6.8) containing 0.25mM sodium sulphate were
9 used for the separation of large PG, versican,
10 aggrecan and perlecan, under associative conditions
11 according to the method of Carney.

12

13 SDS-PAGE was also used to separate the denatured PG
14 and proteins.

15

16 After electrophoretic separation, the samples were
17 transferred onto Hybond ECL-nitrocellulose membrane
18 (Amersham Pharmacia) using a wet blotting unit
19 (BioRad). Membranes were blocked with 5% Milk in TBS
20 pH 7.4 containing 0.1 % v/v Tween-20 and 0.1% sodium
21 azide for 1 hours at room temperature and then
22 incubated with primary antibodies diluted in TBS-
23 Tween 20 for 1 hour at room temperature or overnight
24 at 4°C.

25

26 The primary antibody for versican (12C5) was mouse
27 anti-human at 1/500 dilution (Hybridoma Bank, Iowa
28 City, Iowa). This antibody recognizes the hyaluronic
29 acid binding domain of versican (83). Aggrecan

1 antibody was used at dilution of 1/500 aggrecan
2 (Serotec, HAG7E1). Due to the fact that the exact
3 epitope recognised by this antibody is unknown,
4 additional antibodies were used. Perlcan antibody
5 was used at a dilution of 1/1000 (7B5, Zymed
6 Laboratories). This antibody has been demonstrated
7 to be immunoreactive to non-degraded forms of
8 perlecan (73). MMP1 (41-1E5), inactive MMP9 (7-11C)
9 and TIMP1 (7-6C1) antibodies were all from Oncogene
10 Research Products and used at 1:1000 dilution.

11

12 Some blots were stripped using 100mM 2-
13 mercaptoethanol, 2% SDS and 62.5mM Tris-HCl (pH 6.7)
14 at 56°C for 20 minutes. They were then re-probed
15 using a different antibody.

16

17 A horseradish peroxidase (HRP)labelled secondary
18 antibody (goat anti mouse Ig, Dako) was added.
19 Signal was visualised using the ECLplus (enhanced
20 chemiluminescence) assay (Amersham Pharmacia).

21

22 The same analyses as detailed above were performed
23 using extracts subjected to pre-clearing of the
24 functional modifying antibodies by
25 immunoprecipitation using protein A sepharose
26 according to manufacturer's instructions (Amersham
27 Pharmacia).

28

1 Immunohistochemistry (Frozen sections)

2

3 In additional experiments, immunohistochemical
4 staining for PG was performed on 5 um thick frozen
5 OCT-embedded sections from human lung explants. The
6 slides were blocked by incubating with universal
7 blocking solution for 10minutes at room temperature
8 followed by biotin blocking solution for 10 minutes
9 (Dako). Sections were then rinsed with TBS (0.5 M
10 Tris, pH 7.6, 1.5 M NaCl), and incubated with the
11 primary antibody. After washing with TBS, the tissue
12 was incubated with a 1/200 biotin-labeled goat anti-
13 mouse in TBS for 1 hour, rinsed with TBS and then
14 further incubated with 1/100 alkaline phosphatase-
15 conjugated avidin in TBS for 1 hour. After further
16 washing, sections were developed with Fast Red salt
17 1mg/ml in alkaline phosphatase substrate for 15
18 minutes at room temperature. Sections were counter-
19 stained with Gil's Haematoxylin for 45 seconds, then
20 washed with water. The sections were covered with a
21 thin layer of crystal mount and dried in the oven at
22 37°C, overnight.

23

24 **Therapeutic effect using an in vivo animal model of**
25 **injury: Model of emphysema induced by instillation of**
26 **porcine pancreatic elastase emphysema**

27

28 Female C57/BL6 mice (6-8 weeks old) were instilled
29 intra-tracheally using a metal cannula with 1 IU/g

1 body weight porcine pancreatic elastase (Roche).
2 Mice were sampled at day 10 post instillation and
3 histology examined to verify the presence of air
4 space enlargement. At day 12, mice were treated
5 intra-tracheally with the integrin antibody at 50
6 ug/animal in sterile PBS. Control group was
7 instilled initially with PBS and at day 12 with
8 isotype control IgG1 (50ug/animal). At day 19 post
9 elastase instillation, the animals were sacrificed,
10 bronchoalveolar lavage fluid (BALF) collected and
11 used to quantify the cytokines (KC (murine homologue
12 of human IL8) and active TGFb1) using sandwich ELISA
13 (R & D Systems).

14

15 The lungs were then removed en bloc and formalin-
16 fixed at a pressure of 25cm water, for histological
17 assessment of damage and morphometric analysis (mean
18 linear intercept). Blocks were sectioned at 5um
19 thickness and stained using Haematoxylin and Eosin.
20 Sagittal sections were used from each animal. Images
21 from 10 fields per section at 100x magnification were
22 digitised and analysed using Scion image (NIH).
23 Actual field size was 1.33 (H) x 1.03 (V) mm. The
24 number of alveolar walls intercepting a horizontal
25 and a vertical line was counted. Mean linear
26 intercept was calculated from each field (horizontal
27 and vertical) by dividing the length of the line by
28 the number of intercepts.

29

1 In a follow-up study, female C57/BL6 mice (6-8 weeks
2 old) were instilled intra-tracheally using a
3 microspray device (Penn Century, USA) with 0.2 IU/g
4 body weight porcine pancreatic elastase (Roche).
5 Mice were sampled at day 14 post instillation and
6 histology examined to verify the presence of air
7 space enlargement. At day 14 or 21, mice were
8 treated intra-tracheally using microspray with the
9 integrin antibody at 60 ug/animal in sterile PBS.
10 Control group was instilled initially with PBS and at
11 day 14 or 21 with PBS. For the group treated at day
12 14, the animals were terminated at day 21 as follows:
13 The animals were anaesthetised using sodium
14 pentobarbitone (45mg/kg), paralysed using pancuronium
15 bromide (0.8mg/kg) and tracheostomised and ventilated
16 using a small animal ventilator (Flexivent, SCIREQ,
17 Montreal) at 8ml/kg and a rate of 150 breaths/minute
18 and positive end expiratory pressures (PEEP) of 3.5
19 cmH₂O in pressure limited fashion. The computer-
20 controlled ventilator enables the measurement of
21 pulmonary mechanics (airway resistance, tissue
22 resistance and elasticity, pressure-volume curves) by
23 applying an interrupter signals. For the complex
24 impedance measurements, a signal of 8 seconds
25 containing 19 prime sinusoidal waves with amplitude
26 of 1.6ml/kg between 0.5 and 19.6 Hz is applied. The
27 signals of cylinder pressure and piston volume
28 displacement obtained during the perturbations are
29 low-pass filtered and stored on a computer for

1 analysis using the constant phase model (39-41).
2 Newtonian Resistance or airway resistance (R_{aw}) of
3 the Constant Phase Model represents the resistance of
4 the central airways. Tissue damping (G) is closely
5 related to tissue resistance and reflects the energy
6 dissipation in the lung tissues. The parameter H is
7 closely related to tissue elastance and reflects the
8 energy conservation in the lung tissues.

9

10 The pressure-volume curve is obtained during
11 inflation and deflation in a stepwise manner by
12 applying volume perturbation incrementally during 16
13 seconds. The pressure signal is recorded and the
14 pressure-volume (P - V) curve is calculated from the
15 plateau of each step. The constant K was obtained
16 using the Salazar-Knowles equation and reflects the
17 curvature of the upper portion of the deflation PV
18 curve. Quasi-static Elastance. Quasi-static
19 elastance reflects the static elastic recoil pressure
20 of the lungs at a given lung volume. It is obtained
21 by calculating the slope of the linear part of P - V
22 curve.

23

24 After the measurements, the animals were sacrificed,
25 bronchoalveolar lavage fluid (BALF) collected. The
26 BALF was centrifuged at 2000 rpm for 10min and the
27 supernatants stored at -70°C .

28

1 Histochemistry

2

3 The lungs were then removed en bloc and formalin-
4 fixed at a pressure of 25cm water. The lungs were
5 paraffin-embedded and sectioned at 4 μ m thickness
6 sections. Sagittal sections were used from each
7 animal for histological and immunohistochemical
8 assessment of damage, and morphometric analysis (mean
9 linear intercept, Lm).

10

11 Morphometric assessment of Lm was performed on
12 sections deparaffinated (using xylene and absolute
13 ethanol followed by 90% and 70% and 50% ethanol) and
14 then stained with Haematoxylin and eosin. Images
15 from 10 fields per section were digitised using 10x
16 objective and the field size was 0.83 μ m x 0.63 μ m.

17

18 Histological assessment of elastic fibre damage was
19 performed by staining deparaffinated tissue section
20 (using xylene and absolute ethanol followed by 90%
21 and 70% and 50% ethanol) with Resorcin-Acid Fuschin
22 (Elastin Products, U.S.A.) according to the
23 manufacturer's instructions. Counter staining was
24 performed using 0.5% tartrazine in 0.25% acetic acid.
25 Elastic fibres appear dark red or purple and the rest
26 of the tissue appears yellow.

27

28 Terminal Deoxyribonucleotidyl Transferase (TdT)-**29 Mediated dUTP Nick End Labelling (TUNEL)**

1

2 Tissue sections were deparaffinated using xylene and
3 absolute ethanol followed by 90% and 70% ethanol. The
4 sections were stained using the Red ApopTagTM Kit
5 (Chemicon) according to the manufacturer
6 instructions.

7

8 The principle of this technique relies on the
9 addition of nucleosides at 3'-OH end of a piece of
10 DNA by TdT. The enzyme in the presence of divalent
11 cation will transfer a nucleotide to the 3'-OH end
12 whether it is blunt, protruding or recessed. The
13 labelling tools in TUNEL method are very versatile.
14 The TUNEL method used for detection of apoptosis
15 utilising TdT tagged with digoxigenin-11-dUTP and
16 dATP was used for end-extension of 3'-OH ends of
17 double or single stranded DNA. Rhodamine labelled
18 anti-digoxigenin was then used for
19 immunohistochemical staining. It is worthwhile to
20 mention that the digoxigenin/anti-digoxigenin
21 labelling system is preferable over the avidin/biotin
22 system due to its lower background. The former
23 system signal yield is also 38-fold more intense than
24 the latter. In conjunction with TUNEL, DAPI was used
25 as a fluorescent nuclear counterstain.
26 Quantification of apoptotic nuclei (stained
27 positively) is performed using confocal microscopy
28 using x40 objective. Images were acquired by
29 stacking (4x4) which account for a total area of

1 0.921mm x 0.921mm from a section of 8mm x 8mm. The
2 number of alveolar walls intercepting a horizontal
3 and a vertical line was counted. Mean linear
4 intercept was calculated from each field (horizontal
5 and vertical) by dividing the length of the line by
6 the number of intercepts.

7
8 Positive controls were also used. Sections were
9 deparaffinated using xylene and absolute ethanol
10 followed by 90% and 70% ethanol. Tissue sections
11 were then subjected to DNAs treatment for 10 minutes
12 at room temperature (2000 U/ml in 30mM Trizma Base,
13 pH 7.2, 4mM MgCl₂, 0.1mM DTT). Negative controls
14 were included were sections were incubated only with
15 the nucleotides in the absence of the reaction
16 enzyme.

17
18 Our experiments demonstrate a novel finding which is
19 that that an increase in ECM PGs anabolism can be
20 achieved via functional modification of the cell
21 surface β 1 integrin and to a much lesser extent to
22 neutralising TGF β in both time- and dose-dependent
23 manner in human lung explants and human lung derived
24 cell co-cultures as well as pulmonary derived
25 epithelial cell line. Our experiments have
26 demonstrated that the increase in ECM PGs was
27 partially due to de novo protein synthesis. The
28 changes were accompanied by an increase in TIMP1,
29 inactivation of MMP9 and decrease in MMP1.

1
2 We have also induced emphysematous injury in the lung
3 using porcine pancreatic elastase. Elastase induced
4 a statistically significant two-three fold increase
5 in the mean linear intercept (Lm) accompanied by an
6 increase in lung size. Emphysematous mice treated by
7 intratracheal dose of anti $\beta 1$ integrin at day 12, 14
8 or 21 showed marked reduction in lung size at day 19-
9 21 and 35. The change was accompanied by a
10 significant reduction in the Lm, improvement in lung
11 function and restoration of elastic fibres. The
12 changes were also accompanied by a decrease in cell
13 death. We therefore postulate that $\beta 1$ integrin
14 functional modification may have caused "loosening"
15 of cells from the underlying damaged ECM and thus
16 modified its mechanosensing (shock absorption) in a
17 manner permissible for repair to ensue. This
18 mechanism could be in addition the above mechanisms
19 involving alteration of MMP/TIMP balance.

20
21 Furthermore, porcine pancreatic elastase resulted in
22 a decrease in active TGF $\beta 1$ in the bronchoalveolar
23 lavage which appeared to be reversed by the
24 treatment. The levels of active TGF $\beta 1$ exhibited a
25 statistically significant correlation ($r=0.96$,
26 $p<0.01$) with the Lm.

27
28 All documents referred to in this specification are
29 herein incorporated by reference. Various

1 modifications and variations to the described
2 embodiments of the inventions will be apparent to
3 those skilled in the art without departing from the
4 scope of the invention. Although the invention has
5 been described in connection with specific preferred
6 embodiments, it should be understood that the
7 invention as claimed should not be unduly limited to
8 such specific embodiments. Indeed, various
9 modifications of the described modes of carrying out
10 the invention which are obvious to those skilled in
11 the art are intended to be covered by the present
12 invention.
13
